

APPENDIX A

The Joint Committee for Powder Diffraction Standards (JCPDS) [48]

ZnO, JCPDS file number 00-005-0664

Name and formula

Reference code:	00-005-0664
Mineral name:	Zincite, syn
Common name:	zinc white
PDF index name:	Zinc Oxide
Empirical formula:	OZn
Chemical formula:	ZnO

Crystallographic parameters

Crystal system:	Hexagonal
Space group:	P63mc
Space group number:	186

a (?):	3.2490
b (?):	3.2490
c (?):	5.2050
Alpha (?):	90.0000
Beta (?):	90.0000
Gamma (?):	120.0000

Calculated density (g/cm ³):	5.68
Measured density (g/cm ³):	5.66
Volume of cell (10 ⁶ pm ³):	47.58
Z:	2.00
RIR:	4.50

Status, subfiles and quality

Subfiles: Inorganic
Mineral
Alloy, metal or intermetallic
Common Phase
Forensic
NBS pattern

Quality: Indexed (I)

Comments

Color: White

General comments: Opaque mineral optical data on specimen from Sterling Hill, New Jersey, USA: $R_3R\%=11.8$, $Disp=Std.$, $VHN_{100}=190-219$, Ref.: IMA Commission on Ore Microscopy QDF.

Sample source: Sample from New Jersey Zinc Company, Sterling Hill, New Jersey, USA.

Analysis: Spectroscopic analysis: $<0.001\%$ each of Mg, Si and Ca.

Optical data: $B=2.013$, $Q=2.029$, $Sign=+$

Melting point: $1670(10)^\circ C$

Temperature: X-ray pattern at 26 C.

ZnTiO₃, JCPDS file number 00-026-1500

Name and formula

Reference code: 00-026-1500
Mineral name: Ecandrewsite, syn
PDF index name: Zinc Titanium Oxide
Empirical formula: O₃TiZn
Chemical formula: ZnTiO₃
Second chemical formula: ZnO . TiO₂

Crystallographic parameters

Crystal system: Rhombohedral
Space group: R-3
Space group number: 148
a (?): 5.0787
b (?): 5.0787
c (?): 13.9270
Alpha (?): 90.0000
Beta (?): 90.0000
Gamma (?): 120.0000

Calculated density (g/cm³): 5.16
Volume of cell (10⁶ pm³): 311.10
Z: 6.00

RIR: 2.50

Subfiles and Quality

Subfiles: Inorganic
Mineral
Common Phase
NBS pattern
Quality: Star (S)

This is the quality mark distribution for 340,653 entries published in PDF-4+ Release 2013. Quality is defined by the ability to produce an accurate powder pattern with

known and consistent chemistry, physical properties, and unit cell parameters. The ICDD does over 100 separate checks in its quality review. Star (S), Indexed (I), and Blank (B) marks are in decreasing order of quality. In these cases there is a unit cell and calculated d-spacings which can be compared to experimental d-spacings. Low precision data (O) tend to be historical in nature where d-spacings and intensities were visually estimated resulting in low precision. Rietveld (R) quality marks result from Rietveld refinements where there is a strong agreement with the structure and powder patterns resulting in high quality.

Calculated (C), Prototype (P) and Hypothetical Data (H) all result from calculation *and do not have corresponding experimental data*. The quality of these data are more difficult to ascertain. The user should be cautious using these data.

Comments

Color: Colorless
 General comments: Because of the presence of small amounts of TiO₂ and Zn₂TiO₄ the intensities may have slight errors.
 Sample preparation: Prepared by heating an equimolar mixture of Zn (NO₃)₂ and TiO₂ (anatase) for two weeks at 900 C with remixings and reheatings.
 Additional pattern: To replace 25-671.
 Temperature: Pattern taken at 25 C.

ABSTRACT

Zn(NO₃)₂·6H₂O and C₄K₂O₇Ti·2H₂O with 1:1 and 2:1 M ratios of Zn:Ti in solutions at the pH 10 were irradiated by 180 W microwave radiation for 40 min to form ZnO/TiO₂ nanocomposites, new candidates for photodegradation and photoreduction in UV light with very high efficiency. Upon processing the nanocomposites at high temperatures, pure Zn₂TiO₄ nanocrystals were synthesized only by the 700 °C and 3 h calcination of the 2:1 M ratio Zn:Ti precursors.

1. Introduction

Recently, photocatalytic materials have been intensively studied due to their high activities for hydrogen evolution from water, degradation of pollutants, CO₂ remediation, self-cleaning activity and air purification. Among them, TiO₂ is a good candidate for environmental remedy due to its non-toxic properties, biological and chemical stabilities, strong oxidizer, low cost and long-term stability against corrosion. Its photocatalysis is limited only in the UV range, including fast recombination of electron-hole pairs [1–3]. In order to enhance TiO₂ photocatalytic activities, it is considered to be put together with ZnO which is non-toxic, low cost, easy to be synthesized and wide application [4–7].

In this research, ZnO/TiO₂ nanocomposites were successfully synthesized by a single-step method using microwave radiation (MWR), and were further calcined at high temperature to form Zn₂TiO₄ single phase.

2. Experiment

Zinc nitrate hexahydrate (Zn(NO₃)₂·6H₂O, 0.100 mol) was dissolved in 100 ml de-ionized water to form solution with the pH was adjusted to 10 using NH₄OH. Then 0.100 mol potassium

titanium oxalate dihydrate (C₄K₂O₇Ti·2H₂O) in 100 ml de-ionized water as a whole was slowly added, with keeping the pH 10 throughout the process. The final solution was irradiated with 180 W MWR for two batches (2 × 20 = 40 min) to form precipitates, which were separated, rinsed and dried at 70 °C for 36 h. Another product was synthesized as the above but 0.200 mol Zn(NO₃)₂·6H₂O was used. The products with 1:1 and 2:1 M ratios of Zn:Ti were labeled Anon and Bnon, respectively. They were further calcined at 500, 600 and 700 °C for 3 h, and labeled A500, A600 and A700 for the first and B500, B600 and B700 for the second.

To study photodegradation, 70 ml 5 × 10⁻⁶ M methylene blue (MB) solutions with and without adding each of 1.00 g product were stirred for 1 h in the dark environment to stabilize them, and irradiated with two 18 W UV lamps for 0–150 min. The MB solution without adding of the photocatalytic product was labeled Blank. Decolorization efficiency was calculated at 671 nm wavelength. Similarly, photoreduction of K₂Cr₂O₇ was at 345 nm.

3. Results and discussion

XRD patterns (Fig. 1) of different products were compared with the JCPDS database nos. 00-005-0664 (hexagonal ZnO), 00-004-0477 (TiO₂, tetragonal anatase), 01-077-0014 (cubic Zn₂TiO₄) and 00-039-0190 (cubic ZnTiO₃) [8]. Both ZnO/TiO₂ composites of Anon and Bnon were successfully synthesized by the MWR process. The synthesis of Zn₂TiO₄ single phase was success only by the 700 °C and 3 h calcination of the Bnon. All ZnO and TiO₂ precursors were chemically combined to form pure Zn₂TiO₄.

without residual detection. For B500 and B600, ZnTiO₃ and Zn₂TiO₄ were synthesized, with TiO₂ remains. In this research, A500, A600 and A700 were still to be mixtures of different phases although the calcination temperature was as high as 700 °C.

At the beginning, Zn(NO₃)₂ · 6H₂O and C₄K₂O₉Ti · 2H₂O formed complexes ions in the solutions at the pH 10.

They were processed by MWR to form composites.

Upon calcination at 500, 600 and 700 °C, different products were synthesized.

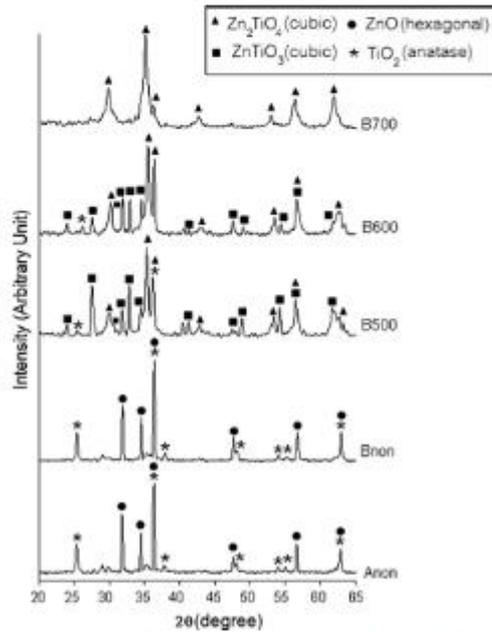

Fig. 1. XRD patterns of Anon, Bnon, B500, B600 and B700.

A number of nanoparticles with different orientations in space were characterized by EM. Before calcination, Bnon (Figs. 2a and 3a) was composed of very tiny particles with < 10 nm. At 500 °C calcination (Figs. 2b and 3c, d), these nanoparticles grew up with the presence of faces and angles, specified as crystals. Further increasing the calcination temperature to 600 °C (Fig. 2c) and 700 °C (Figs. 2d and 3e), the products respectively became 25 nm and 80–100 nm nanocrystals with smooth surfaces. A SAED pattern of Bnon (Fig. 3b) presents bright concentric rings, diffracted from very tiny particles with different orientations, and specified as ZnO/TiO₂ nanocomposites [8]. At 700 °C calcination (Fig. 3f), the pattern was still concentric rings but diffraction spots were moved apart—suggested to be diffracted from a number of better crystals with different orientations, corresponding to Zn₂TiO₄ [8].

Decolorization efficiency (Fig. 4a) of MB in the solutions containing Anon and Bnon exhibited much higher photocatalytic activities than those of the B700 and Blank solutions. B500 and B600 were mixtures of ZnTiO₃, Zn₂TiO₄ (deficiency in photocatalysis) and TiO₂, thus they were not appropriate for studying. Photodegradation of MB in the Anon and Bnon solutions was much the same performance and continuously increased with the lengths of time. As 150 min passed, decolorization efficiencies of both were very close to 100%. The higher photoactivity was enhanced by the higher electron-hole separation rate and the formation of p–n junctions of the ZnO/TiO₂ nanocomposites [3,9]. The photogenerated electrons could easily diffuse from the inner

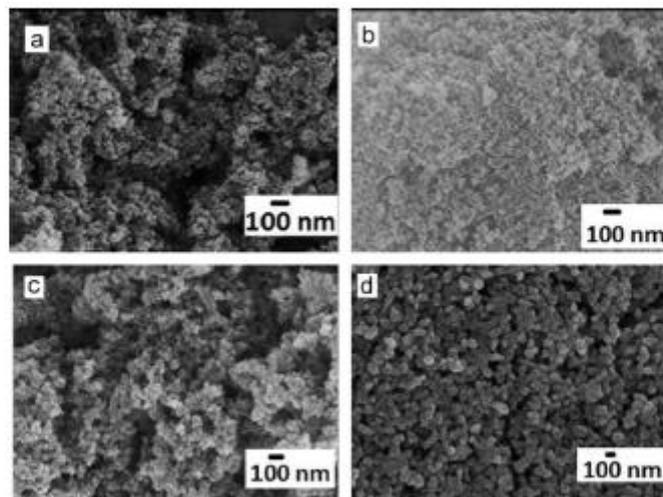

Fig. 2. SEM images of (a–d) Bnon, B500, B600 and B700, respectively.

regions to surfaces of composited nanograins to promote photocatalysis. The higher photocatalytic activity of ZnO/TiO₂ nanocomposites was controlled by the role of ZnO on the surface of TiO₂ nanoparticles (Fig. 5), relating to the diffusion of electrons and holes in conduction and valence bands (CB, VB) with different energy levels of the couples. There are a number of p-n junctions containing in the ZnO/TiO₂ nanocomposites. At equilibrium, an electric field formed inside, which led the negative and positive

charges to be in the p-type ZnO and n-type TiO₂, respectively. Furthermore, the photogenerated electrons in the CB of ZnO diffused into the CB of TiO₂. Concurrently, the photogenerated holes in the VB of TiO₂ diffused into the VB of ZnO. This efficient charged separation increases lifetime of the charged carriers and enhances the efficiency of the interfacial-charged diffusion process [3,10]. Holes combined with H₂O to form [•]H and [•]OH radicals. Concurrently, electrons diffused to the adsorbed O₂ to

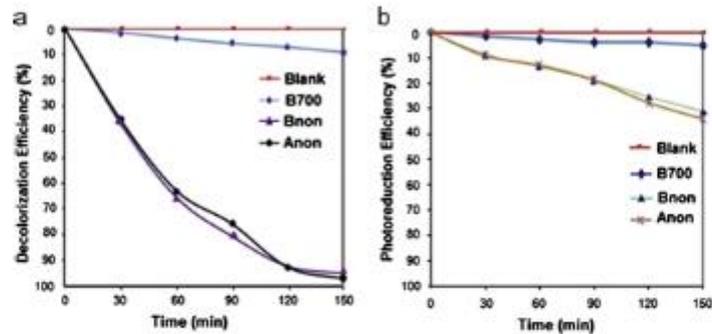

Fig. 4. (a) Photodegradation of MB and (b) photoreduction of $(Cr_2O_7)^{2-}$ by ZnO/TiO₂ nanocomposites and Zn₂TiO₄ comparing to the Blanks.

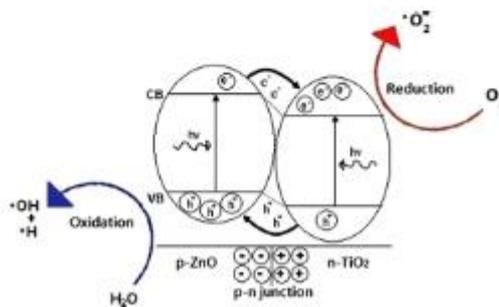

Fig. 5. Schematic diagram for photocatalysis of ZnO/TiO₂ nanocomposites.

form activated $\cdot O_2^-$ with subsequent transforming of water molecules into hydroxyl radicals. These oxidative species could effectively break down toxic organic substances back into original chemical forms of CO₂ and H₂O creating a cleaner and safer environment [11]. If the processes were not possible, electron-hole pairs would recombine together to generate heat inside or on surfaces of the composites.

In case of photoreduction of $(Cr_2O_7)^{2-}$ ions (Fig. 4b), both Anon and Bnon nanocomposites indicated the highest Cr(VI) reduction caused by the diffusion of electrons and holes at the ZnO/TiO₂ interfaces, and Cr(VI) combined with the photogenerated electrons to form Cr(III). The enhanced activity for Cr(VI) reduction was influenced by the difference of VB and CB energy levels of ZnO and TiO₂ to promote charged separation and to inhibit electron-hole recombination. The reduction could be inhibited by the formation of new electron-hole recombination centers, high temperature calcination to enlarge the particles and particle aggregation [11], including phase transformation.

4. Conclusions

A number of ZnO/TiO₂ nanocomposited particles were successfully synthesized by a microwave radiation through an aqueous solution containing Zn(NO₃)₂·6H₂O and C₄K₂O₅Ti·2H₂O at the pH 10, and the further transformation of the nanocomposites to Zn₂TiO₄ nanocrystals by high temperature calcination. The nanocomposites showed the highest promising potential for water treatment with high efficiency.

Abstract ZnO nanostructure materials doped with different La contents were synthesized by sonochemical method. The products were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), Raman spectroscopy, and Fourier transform infrared spectroscopy (FTIR). In this research, XRD patterns of pure ZnO and La-doped ZnO are specified as hexagonal wurtzite ZnO structure with no detection of La₂O₃ phase. SEM and TEM characterization revealed the flower shape of pure ZnO built-up from petals of hexagonal prisms with hexagonal pyramid tips. Upon doping with La, the flower-shaped ZnO is broken into individual 1D prism-like nanorods. Photocatalytic activities of the as-synthesized products were determined by measuring the degradation of methylene blue (MB) under ultraviolet-visible (UV) light irradiation. Among them, the 2.0 mol% La-doped ZnO shows better photocatalytic properties than any other products.

1 Introduction

Semiconductors doped with rare earth (RE) elements are technologically significant materials. They are promising materials used as optoelectronic devices and receive considerable interest for a number of applications, such as phosphors, display monitors, X-ray imaging, scintillators, optical communication, and fluorescence imaging due to their particular 4f–5d and 4f–4f electron transitions which are different from other elements. RE (III) ions are recognized as excellent candidates for luminescence centers of the doped semiconductors to tailor emission color, especially to develop red, green, and blue (RGB) radiations. To dope with RE³⁺ as luminescent centers, emission properties of semiconductors can be tailored toward selected wavelength of visible region, which is very important for a variety of applications, including multicolor emission of light-emitting devices [1–5].

Zinc oxide (ZnO) is one of the II–VI semiconducting materials. It has wide direct band gap of 3.37 eV and large exciton binding energy of 60 meV at room temperature. ZnO gets increasing attention due to its excellent electrical and optoelectronic properties. It can be used for a wide range of application, such as solar cells, gas sensors, optoelectronic devices, and surface acoustic waveguides [6–8]. Moreover, it exhibits better performance in degrading of various environmental pollutants: pesticides, detergents, dyes, and volatile organic compounds by transforming into carbon dioxide, water, and mineral acids under ultraviolet-visible (UV) light irradiation [6, 9]. ZnO doped with RE³⁺ is related to the surface states that favor energy transfer from ZnO to RE³⁺ and shows well-defined narrow optical transition between the spin orbit levels split under different manifold weak crystal fields [1, 10]. Various physical and chemical routes were used to synthesize

RE³⁺-doped nanostructured material: electrochemical deposition [1], hydrothermal method [2, 4, 6], chemical vapor deposition (CVD) [3], sol-gel method [5, 10, 11], precipitation [9], solution combustion [12], and magnetron sputtering [13].

In this research, a facile route of sonochemical synthesis of La-doped ZnO nanostructure materials at low temperature was created. A possible mechanism on the growth of La-doped ZnO nanostructure was explained. In the end, the photocatalytic performance of pure ZnO and La-doped ZnO was investigated. It was found that La-doped ZnO showed better photocatalytic performance than pure ZnO.

2 Experimental

Zinc nitrate hexahydrate (Zn(NO₃)₂·6H₂O) as zinc source, lanthanum nitrate hexahydrate (La(NO₃)₃·6H₂O) as lanthanum source, and sodium hydroxide (NaOH) were used without further purification.

To synthesize 0 mol%, 0.4 mol%, 1.0 mol%, and 2.0 mol% La-doped ZnO, 0.005 mol (Zn(NO₃)₂·6H₂O and 0, 0.4, 1.0, and 2.0 mol% La(NO₃)₃·6H₂O were dissolved in 100-ml deionized water under continuous stirring until complete dissolution. Subsequently, 3 mol·L⁻¹ NaOH solution was slowly dropped into these solutions until their pH reached 10 and the solutions became colorless. Each solution was agitated by an ultrasonic wave of Bandelin Sonorex Super RK 102 H at a frequency of 35 kHz for 5 h. The as-synthesized precipitates were separated by filtration and washed with water and ethanol several times. All the products were dried and collected for further characterization.

The products were characterized by X-ray diffraction (XRD) by a Philips X'Pert MPD X-ray diffractometer equipped with Cu K α radiation over a range of 15°–60° using a scanning rate of 0.02 (°)·s⁻¹. The morphologies and elemental component were recorded by field emission scanning electron microscopy (FE-SEM) carried out using a JEOL JSM 6335F SEM at 20 kV and an energy-dispersive X-ray spectroscopy (EDX) analyzer. Transmission electron microscopic (TEM) images were taken on a JEOL JEM 2010 TEM with an acceleration voltage of 200 kV. The vibration modes were determined by Fourier transform infrared (FTIR) spectroscopy and Raman spectroscopy. The FTIR spectra were recorded on a PerkinElmer RX spectrometer with KBr as a diluting agent and operated in the wave number range of 400–4000 cm⁻¹ with 4 cm⁻¹ resolution. Raman spectroscopy (HORIBA Jobin-Yvon T64000) was operated using 30-mW and 632.8-nm wavelength Helium-Neon red laser.

Photocatalytic activities of the as-synthesized products were determined by specifying the degradation of methylene blue (MB) in aqueous solutions under a visible radiation of UV lamp. The 150 mg photocatalyst was suspended in a 150 ml of 1 × 10⁻⁵ mol·L⁻¹ MB aqueous solution, which was magnetically stirred for 30 min in the dark to establish an adsorption-desorption equilibrium of MB on surface of the photocatalyst. The UV lamp was turned on to initiate photocatalysis. The solution was analyzed by ultraviolet-visible spectroscopy (UV-Vis, PerkinElmer Lambda 25 spectrometer) with λ_{\max} of 664 nm. Decolorization efficiency was calculated using:

$$\text{Decolorization efficiency} = \frac{C_0 - C_t}{C_0} \times 100\% \quad (1)$$

where C_0 is the initial concentration of MB and C_t is the concentration of MB after UV irradiation for the length of time (t).

3 Results and discussion

Figure 1a shows XRD patterns of La-doped ZnO with different lanthanum contents. XRD pattern of the as-synthesized ZnO product can be indexed to hexagonal wurtzite ZnO structure corresponding to the database of JCPDS No. 36-1451. When lanthanum was doped into ZnO matrix, diffraction peaks of the doped products are almost similar to those of undoped hexagonal ZnO crystal. Their crystalline structure remains unchanged, which indicates that La³⁺ uniformly disperses across the hexagonal ZnO matrix [4, 14]. Furthermore, positions of the three main diffraction peaks (Fig. 1b) evidently shift to the smaller Bragg angle with an increase in the concentration of La³⁺ from 0 mol% to 2.0 mol%. Possibly, the covalent radius of La³⁺ (0.106 nm) is larger than that of Zn²⁺ (0.06 nm) [2, 11, 13, 14]. In this research, the unit cell parameters of pure ZnO and La-doped ZnO are summarized in Table 1. They increase with the increase in La content, in accordance with the report of Anandan et al. [15]: the unit cell parameters of ZnO, 0.5 mol% La-doped ZnO, and 1.0 mol% La-doped ZnO are as follows: $a = 0.32480$, 0.32590 , and 0.32670 nm, and $c = 0.52050$, 0.52170 , and 0.52180 nm, respectively.

The products were diluted with potassium bromide in the ratio of 1:100 for FTIR analysis. Figure 2 shows FTIR spectra of 0 mol%–2.0 mol% La-doped ZnO products. The strong absorption bands at 426 and 565 cm⁻¹ are attributed to the Zn–O stretching vibration of wurtzite hexagonal-type ZnO crystal [16, 17], belonging to the oxygen sublattice (E_{2g}) vibration and oxygen vacancies of wurtzite ZnO crystal, respectively [18]. The band at 1385 cm⁻¹ is specified as hydrogen-related defects on surface of ZnO

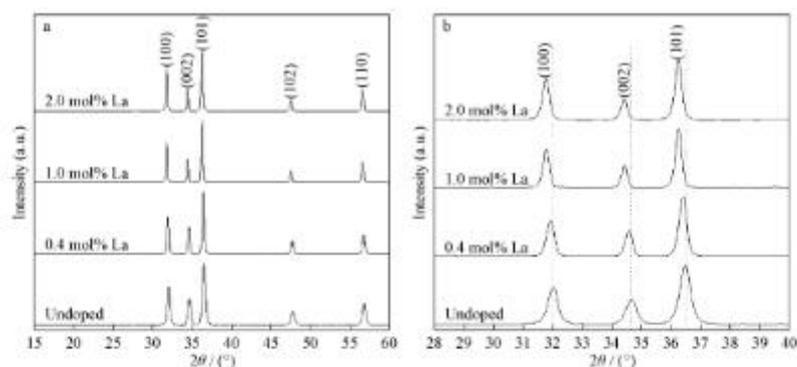

Fig. 1 XRD patterns of pure ZnO and La-doped ZnO over 2θ range of **a** 15° – 60° and **b** 28° – 40°

Table 1 Lattice parameters of present products

Products	Lattice parameter/nm	
	<i>a</i>	<i>c</i>
Pure ZnO	0.32456	0.52050
0.4 mol% La–ZnO	0.32536	0.52137
1.0 mol% La–ZnO	0.32695	0.52372
2.0 mol% La–ZnO	0.32698	0.52375

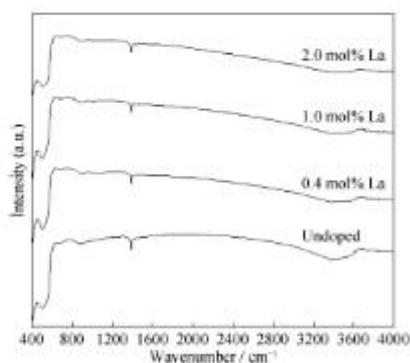

Fig. 2 FTIR spectra of pure ZnO and La-doped ZnO synthesized by sonochemical method

[19]. The broad absorption bands at 3013 – 3633 cm^{-1} are the O–H stretching vibration of adsorbed water on ZnO surface [16–18].

Figure 3 shows Raman spectra of the as-synthesized undoped and La-doped ZnO products. The polar optical branches of A_1 and E_1 are split into longitudinal and

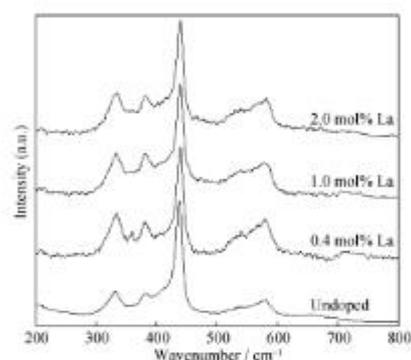

Fig. 3 Raman spectra of pure ZnO and La-doped ZnO synthesized by sonochemical method

transverse optical (LO and TO) components. The peak corresponding to ZnO nonpolar optical phonon high E_2 mode is detected at 437 cm^{-1} [6, 10, 11], including the A_1 symmetry with TO mode at 378 cm^{-1} [6, 19]. The peak at 329 cm^{-1} for ZnO corresponds to the E_{2H} – E_{2L} mode [7, 10]. The peak centering at 583 cm^{-1} is indexed as the E_1 symmetry with LO mode [6, 19]. In this research, Raman spectra of La-doped ZnO agree well with those of pure ZnO with a decrease in the intensity of the peaks. The peak of E_2 mode is significantly restricted due to the loading of lanthanum, which leads to the existence of ZnO lattice [6]. Compared to those of pure ZnO, the E_{2H} modes of La-doped ZnO are blueshifted from 437 to 441 cm^{-1} , with a decrease in the intensity [10, 11, 19]. The blueshift is attributed to the residual stress along the c -axis due to the lattice distortion [10, 11]. The E_{1L} peak centered at 580 cm^{-1} of La-doped ZnO products is the result of

impurities and the formation of defects such as oxygen vacancies and Zn interstitial atoms [7, 10].

Morphologies of the products were investigated by FE-SEM as shown in Fig. 4. SEM image of pure ZnO product shows uniform flower-shaped built-up of hexagonal prisms with hexagonal pyramid tips. The surface of the hexagonal prism petals of flower-like ZnO is very smooth. For each flower, several hexagonal pyramid ZnO petals are grown out of the same distinguished ZnO nucleation site through their base and formed flower-like morphology. The hexagonal pyramid petals of flower-like ZnO are broken into individual 1D prism by La doping. Upon doping with La up to 2.0 mol%, the product is transformed into a large number of ZnO nanorods. Furthermore, small nanoparticles of ZnO crystal are also detected. In addition, EDS was used to determine elemental constituents of La³⁺/ZnO composites, which show signals of Zn at about 1.01, 8.63, and 9.57 keV, oxygen at about 0.53 keV, and La at about 0.84, 4.65, 5.04, and 5.40 keV.

Figures 5 and 6 show TEM images and SAED patterns of the pure ZnO and 2.0 mol% La-doped ZnO products. They are composed of homogenous nanorods with an average diameter of 15–25 nm. SAED patterns of pure ZnO and 2.0 mol% La-doped ZnO products taken from individual single nanorods of both show bright spots of electron diffraction which reveals single-crystalline nature of ZnO and La-doped ZnO nanorods with the electron beam pointing along the same $[-110]$ zone axis. The SAED patterns can be indexed as the (110) plane which is parallel to the preferential growth along the $[001]$ direction of ZnO and La-doped ZnO nanorods. In general, anisotropic growth direction of ZnO is determined by interfacial free energy as well as dissolution ability in water. The growth is also controlled by the relative growth velocity of different planes. Moreover, the polar faces with surface

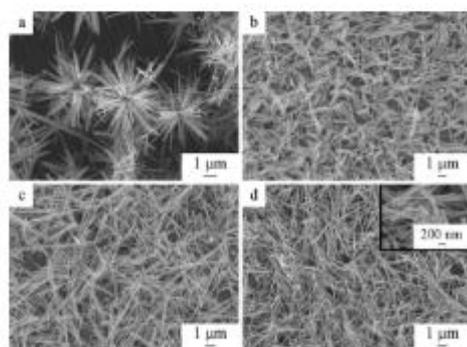

Fig. 4 SEM images of **a** pure ZnO, **b** 0.4 mol% La-doped ZnO, **c** 1.0 mol% La-doped ZnO, and **d** 2.0 mol% La-doped ZnO

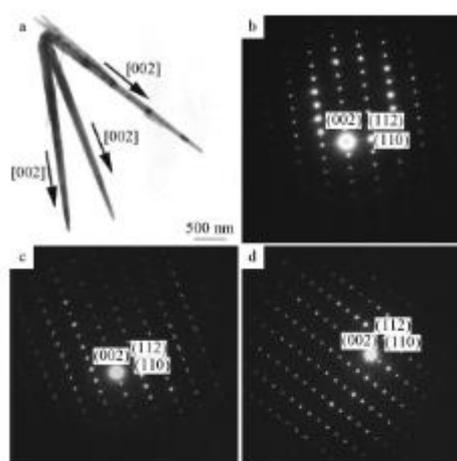

Fig. 5 TEM image **a** and SAED patterns **b–d** of undoped ZnO

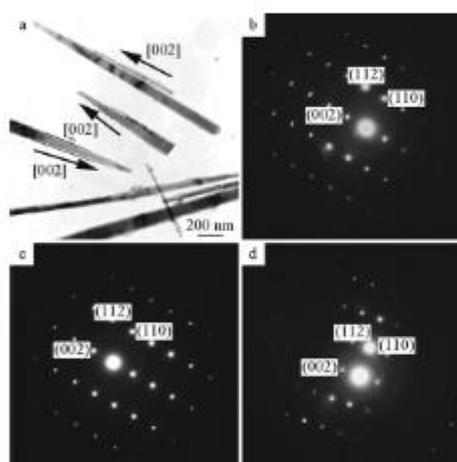

Fig. 6 TEM image **a** and SAED patterns **b–d** of 2.0 mol% La-doped ZnO

dipoles are less thermodynamically stable than those of nonpolar faces, which often undergo atomic rearrangement to minimize their surface energies and tend to grow more rapidly. Interestingly, morphologies of the as-synthesized 1D ZnO nanomaterials are fully consistent with the ideal hexagonal ZnO crystal model with the crystal growth velocity of various crystal facets of $[0001] > [01\bar{1}] > [01\bar{1}0] > [000\bar{1}]$ [20, 21]. Since the (0001) face has higher symmetry (C_{6v}) and specific surface free energy

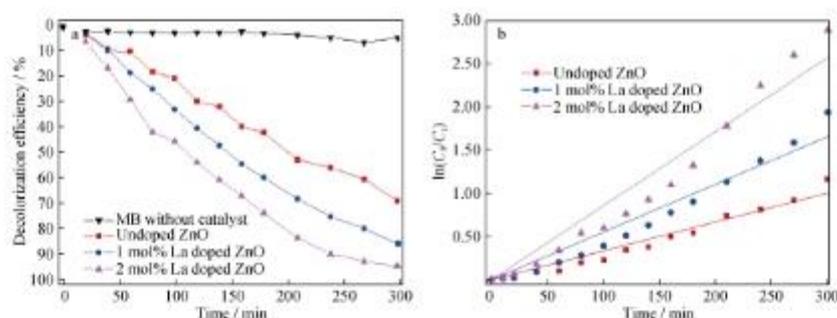

Fig. 7 Decolorization efficiency **a** and reaction kinetics **b** of present products

than any other faces [22], the growth rate along the [0001] direction is the highest, about twice of the [01–10] crystal direction, and the growth rate along the [01–1–1] is in the middle. Thus, the as-grown 1D ZnO nanomaterials grow along the [0001] direction bound with the six crystallographic {01–10} family planes [1, 20, 21].

Figure 7a shows the photocatalytic activities of pure ZnO, 1.0 mol% La-doped ZnO, and 2.0 mol% La-doped ZnO products. The degradation of MB is hardly detected without any catalyst under UV radiation. It is suggested that the photoinduced self-sensitized photolysis of MB could be neglected. The degradation efficiency of MB solution over pure ZnO is about 68.22 % within 300 min. However, the degradation efficiency is significantly improved under the same condition after La^{3+} was doped in the ZnO matrix. The photocatalytic efficiencies of 1.0 mol% La-doped ZnO and 2.0 mol% La-doped ZnO are enhanced to 85.38 % and 94.58 % within 300 min, respectively. To better understand the reaction kinetic of MB degradation catalyzed by pure ZnO and La-doped ZnO products, the relationship between $\ln(C_t/C_0)$ and the irradiation time for MB degradation was studied (Fig. 7b). The photocatalytic degradation curves fit well with the first-order linear equation. The 2.0 mol% La-doped ZnO exhibits the highest rate constant ($k = 8.66 \times 10^{-3} \text{ min}^{-1}$). It is approximately 2.6 times larger than that of pure ZnO ($k = 3.35 \times 10^{-3} \text{ min}^{-1}$).

Photocatalytic activity of the photocatalyst is mainly determined by several factors: morphology, Brunauer–Emmett–Teller (BET) surface area, crystalline facet, and dopant [6, 16, 18, 23–25]. Spherical ZnO has higher photocatalytic activity than flower-like ZnO, because it has rather higher specific surface area and pore volume than nanostructured flower shape [23]. The exposed crystalline face is noticeably different for ZnO particles with different morphologies: the more specific sites they have, the more their activities become. The unique ZnO nanodisks with high (0001) facet population and small surface area show

better photocatalytic activity than other crystalline faces [24, 25]. In this work, single-crystalline nature of ZnO and La-doped ZnO nanorods is of preferential growth along the [001] direction. Therefore, La dopant has the influence on the photocatalytic efficiency of ZnO powder. The 2.0 mol% La-doped ZnO shows higher photocatalytic activity than other products, due to the concentration of oxygen defects on the surfaces of the doped nanocrystals [18].

4 Conclusion

In this research, La-doped ZnO was successfully synthesized via a sonochemical method. The experimental results demonstrate that the as-synthesized 2.0 mol% La-doped ZnO has an excellent photocatalytic activity than pure ZnO for degradation of MB under UV irradiation. This research may provide guidance for the treatment of organic pollutants.

Nanorods

ABSTRACT

One-dimensional La doped ZnWO₄ nanostructures have been synthesized by hydrothermal method. The effect of various La contents doped ZnWO₄ samples on phase, morphologies and optical properties was investigated and characterized by X-ray diffraction (XRD), field scanning electron microscopy (FESEM), transmission electron microscopy (TEM), high resolution transmission electron microscopy (HRTEM), Raman and UV–visible spectroscopy, respectively. The results of XRD, SEM and SAED revealed that all products were one-dimensional monoclinic ZnWO₄ nanorods while doped La³⁺ constants into ZnWO₄ lattice. The observation of TEM and HRTEM showed that the obtained La³⁺ doped ZnWO₄ with different La constants were homogenous nanorods shapes with grow along [021] direction. The optical property result showed that La³⁺ doped ZnWO₄ is a red shifted absorption when comparing to pure ZnWO₄.

1. Introduction

In the past decade, ZnWO₄ has been widely researched because of its interesting in chemical and physical properties such as laser hosts, magnetic, scintillated, luminescent and catalytic properties and potential applications such as optical fibers, scintillator materials, magnetic properties, and

E-mail address: phuruangrat@hotmail.com (A. Phuruangrat).

heterogeneous catalysis [1–3]. ZnWO_4 is a materials in wolframite structure and belongs monoclinic with C_{2h} point group symmetry and P2/c space group. There are two formula units per primitive cell, having the lattice parameters $a = 4.69263 \text{ \AA}$, $b = 5.72129 \text{ \AA}$, $c = 4.92805 \text{ \AA}$ and $\beta = 90.6321^\circ$. The presence of two non-equivalent oxygen atoms is responsible for three pairs of Zn–O and W–O bonds, having different lengths. Thus, both Zn and W ions are surrounded by six oxygen atoms coordination, forming distorted ZnO_6 and WO_6 octahedral coordination which either edge-sharing ZnO_6 octahedron or edge-sharing WO_6 octahedra are corner-linked by zigzag chains in parallel to [001] [1,2,4].

To increase the luminescence efficiency of phosphor, researchers have tried various approaches including modify phosphor particle size and surface morphology, adding conductive materials, mixing flux materials and doping a sensitizer to enhance excitation energy absorption and energy transfer to the activator [5]. Doping method is a suitable synthesis method to increase the optical efficiency of oxide phosphor, rare-earth (RE) with their particular 4f–5d and 4f–4f electronic transition was used due to their unique optical transitions happen between the spin orbit levels split under the different manifolds weak crystal field and promising applications in optoelectronic devices [6–9]. By doping with RE^{3+} ions, it improves the luminescence efficiency by energy transfer processes [10]. For example, Anandan et al. report a high photocatalytic activity in the degradation of organic contaminants of La-doped TiO_2 due to the suppression of electron-hole recombination, large content of oxygen vacancies, and strong absorption of OH^- ions on the surface of the catalyst [11]. Jia et al. shows a strong emission peak centering at around 405 nm of La-doped ZnO which exhibited a red shift compared with the near band emission of pure ZnO because the incorporation of La^{3+} ions [12]. Here, we report one-dimensional La doped ZnWO_4 with differences La contents nanostructures by hydrothermal method. The effects of La doping on the structural and optical properties of ZnWO_4 were also investigated and discussed in detail.

2. Experimental procedure

All the chemicals used in the experiment, including zinc nitrate hexahydrate ($\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$), lanthanum nitrate hexahydrate ($\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$), sodium tungstate dihydrate ($\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$) were used as zinc, lanthanum, tungsten sources, respectively are of analytic grade reagents without further purification.

In a typical procedure, the mixture containing 0.005 mol $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and different amount of $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ (0.2, 0.4, 0.6, 1.0 and 2.0 wt%) was dissolved into 60 ml deionized water under rigorous stirring for 30 min. Then, 0.005 mol $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ in 20 ml deionized water was added and the mixture solution was transferred into a Teflon lined steel autoclave of 100 ml, and the autoclave was heated at 180°C for 24 h. Afterward, the autoclave was cooled to room temperature gradually. The white precipitate was washed with ethanol and distilled water three times. Then, it was dried at 80°C for 12 h.

The products were characterized by X-ray diffraction (XRD) on a Philips, XPert MPD X-ray diffractometer equipped with $\text{Cu K}\alpha$ radiation over a range from 10° to 60° . The scanning electron microscopy (SEM) images were carried out using a JEOL JSM-6335F field emission scanning electron microscopy (FESEM). Transmission electron microscopy (TEM) and high-resolution field emission transmission electron microscope (HRTEM) images and selected area electron diffraction (SAED) pattern were taken on a JEOL JEM-2010 transmission electron microscopy with an acceleration voltage of 200 kV. Fourier transform infrared spectra (FT-IR) were recorded on a Bruker Tensor 27 FT-IR spectrometer with a KBr disk. Raman spectra were recorded on HORIBA JOBIN YVON T64000 Raman spectrometer with 50 mW and 514.5 nm wavelength Ar laser. UV-visible absorption spectra were recorded on a PerkinElmer, Lambda 25 UV-visible spectroscopy in wavelength range 200–800 nm.

3. Results and discussion

The phase structure of the products were examined by XRD. Fig. 1 shows XRD patterns of as-prepared pure ZnWO_4 and La-doped ZnWO_4 samples. For undoped ZnWO_4 , all diffraction peaks can be readily indexed to the pure monoclinic ZnWO_4 structure with space group of P2/c and comprises

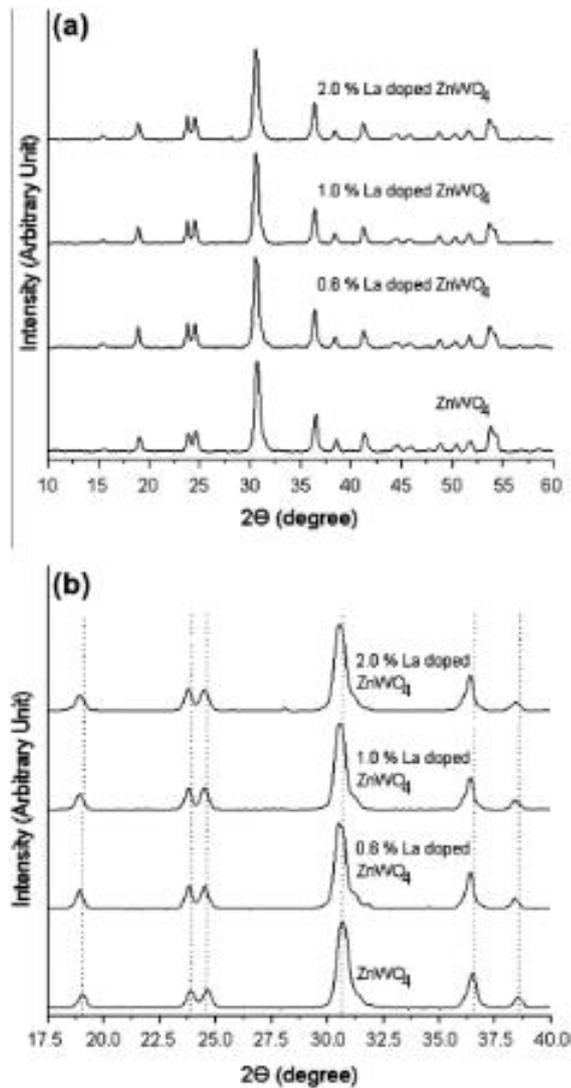

Fig. 1. XRD pattern of as-prepared 0–2% La doped ZnWO_4 samples synthesized by hydrothermal method.

infinite zigzag chains, running parallel to $[001]$, of either edge-sharing ZnO_6 octahedron or edge-sharing WO_6 octahedra [1,2,14] which was in good agreement with JCPDS No. 15-0774 [13]. For La-doped ZnWO_4 , they are still indexed the ZnWO_4 and no detected diffraction peaks of La_2WO_6 , La_2O_3 or other impurity phases in La-doped ZnWO_4 samples. It indicated that the existence of La^{3+} did not significantly influence the phase and crystallization of the products and suggested that La^{3+} ions would uniformly substitute into the Zn^{2+} sites or interstitial sites in ZnWO_4 lattice. Fig. 1b of La-doped ZnWO_4 with compared to the pure ZnWO_4 in $2\theta = 17.5\text{--}40^\circ$, it can be seen that all peaks were slightly shifted

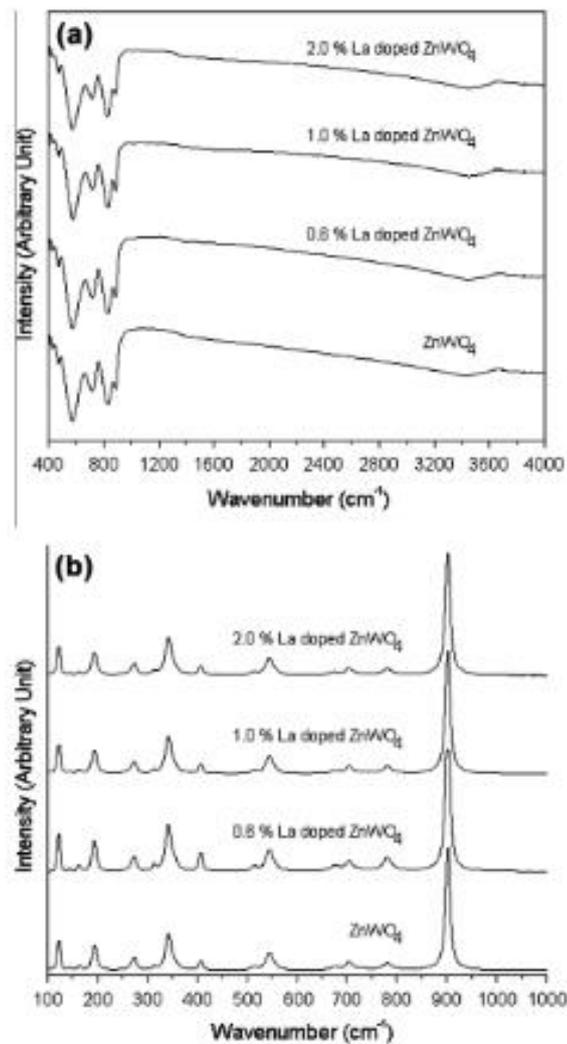

Fig. 2. FTIR and Raman spectra of 0–2% La-doped ZnWO₄.

towards smaller diffraction angle. They suggested that the larger La³⁺ substitutes the smaller Zn²⁺ site partly so that the slightly shifting peak towards smaller diffraction angle. The ionic radius of La³⁺ (1.06 Å) is slightly larger than that of Zn²⁺ (0.74 Å), but much larger than that of W⁶⁺ (0.62 Å) in 6-fold coordination [15–17], so La³⁺ prefers to locating in Zn²⁺ sites without inversion center. As the amount of La³⁺ increases, it is observed that the corresponding XRD peaks move to lower degree according to previous reports which confirm that La³⁺ ions are inserted in ZnWO₄ lattice cell [11,12,15–19].

FTIR spectra of the La-doped ZnWO₄ samples with various concentration of La present in Fig. 2a. The products were mixed and diluted 10 times with potassium bromide (KBr). The background

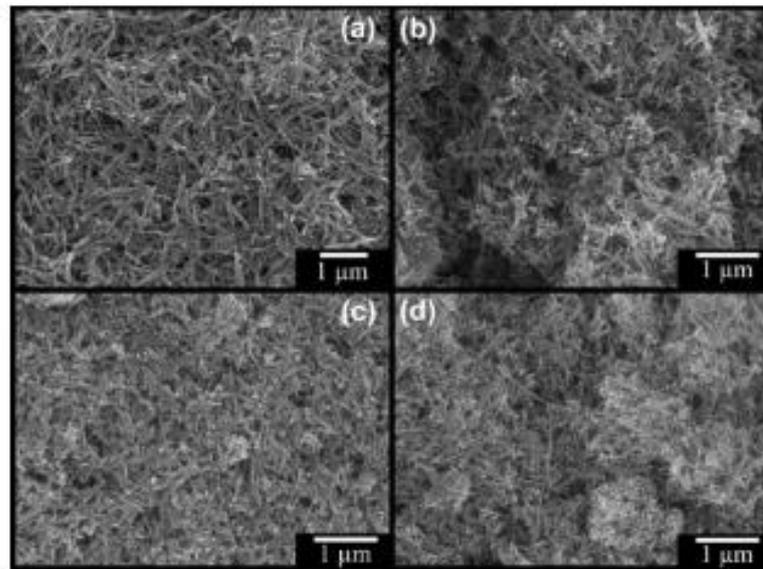

Fig. 3. SEM images of (a) 0%, (b) 0.4%, (c) 1% and (d) 2% La doped ZnWO_4 .

spectrum recorded using KBr was subtracted from the products spectrum. The ZnWO_4 samples show six main absorption bands at $430\text{--}1000\text{ cm}^{-1}$. The absorption bands at 834 and 877 cm^{-1} can be due to the stretching modes of W–O in WO_6 octahedra. The bands at 610 and 532 cm^{-1} were due to symmetrical vibrations of bridge oxygen atoms of the Zn–O–W groups. The absorption bands at 473 and 430 cm^{-1} can be assigned to symmetric and asymmetric deformation modes of W–O bonds and Zn–O bonds in WO_6 and ZnO_6 octahedra, respectively [1,2,20,21]. These vibrations could be identified to the synthesized ZnWO_4 . Obviously, the broad bands in the 3400 cm^{-1} is assigned to the O–H vibrations of H_2O molecule. It is also evident that the prepared samples contain a significant amount of surface-adsorbed water and some structural water.

Raman spectra of wolframite ZnWO_4 has 36 lattice vibration modes as $\Gamma = 8A_g + 10B_g + 8A_u + 10B_u$ by group theory. Only 18 modes of $8A_g$ and $10B_g$ are Raman active while 15 modes of $7A_u$ and $8B_u$ are infrared (IR) active, and 3 modes of $1A_u$ and $2B_u$ are acoustic vibrations. Raman vibration of monoclinic wolframite ZnWO_4 was referred to the incompressibility of WO_6 octahedrons with respect to the ZnO_6 octahedrons [2,22,23]. Raman spectra of the samples in the range $100\text{--}1000\text{ cm}^{-1}$ are shown in Fig. 2b. Their peaks were assigned to the stretches of the W–O bands. The peak at 900 cm^{-1} was interpreted as an antisymmetric bridging mode associated with the tungstate chain. The bands about 300 cm^{-1} were assigned to the modes of terminal WO_2 group. The W–O bonds of intermediate length are characteristic of bridging W–O bonds and are assigned to Raman mode stretching wavenumbers in the $700\text{--}1000\text{ cm}^{-1}$ [2,23–25].

The general morphologies of the as-prepared La-doped ZnWO_4 products are examined by scanning electron microscopy (SEM) and transmission electron microscopy (TEM) observation. Fig. 3 shows the SEM images of La-doped ZnWO_4 with difference La contents. As can be seen from Fig. 3a, it reveals that the as-synthesized pure ZnWO_4 product consists of uniform nanorods and no detection of other shapes. It can be seen that these nanorods have a uniform diameter of about 20 nm and lengths up to $0.5\text{--}1\text{ }\mu\text{m}$. The La-doped ZnWO_4 samples can be found that the morphologies of sample (Fig. 3b–d) are almost different. They found that the length of nanorod was decreased when increased the content of La doping. Finally, the completely short nanorods were produced at 2% La-doped ZnWO_4 . In

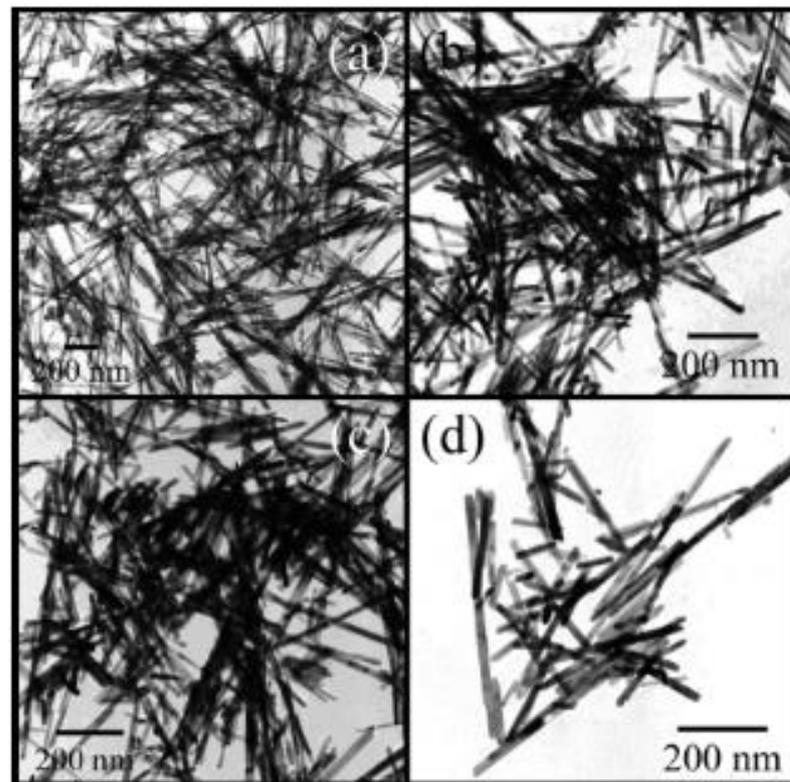

Fig. 4. TEM images of (a) 0%, (b) 0.4%, (c) 1% and (d) 2% La doped ZnWO_4 .

addition, the EDS spectra show the chemical composition of sample which revealed the presence elementary components of Zn, W and O in ZnWO_4 and Zn, La, W and O in La-doped ZnWO_4 .

The morphologies of the as-prepared La doped ZnWO_4 samples were further studied by TEM. Fig. 4 shows the morphologies of the as-synthesized samples were strongly dependent on La content doping. The ZnWO_4 without La doping as shown in Fig. 4a shows the uniform rod-shaped crystals and a majority of the crystals had exceeded 1500 nm in length. Fig. 4b–d shows the TEM image of La-doped ZnWO_4 for La = 0.4%, 1% and 2% by weight. Increasing of La content in ZnWO_4 , the products are still one-dimensional ZnWO_4 nanostructures but not uniform in length. The products are mixture of short and long nanorod-shaped crystals can be seen. For 2% La-doped ZnWO_4 , with two length ranges of 100–200 nm and 400–800 nm were observed.

To understand the preferential orientation growth, ZnWO_4 nanorods and 2% La-doped ZnWO_4 nanorods have been further studied using high resolution transmission electron microscope (HRTEM) and selected area electron diffraction (SAED) techniques and the results were shown in Figs. 5 and 6. The pure ZnWO_4 sample consists of uniform nanorods with average width and length of 20 nm and >1500 nm (aspect ratio of >75). Each nanorod is straight and perfect over their entire lengths. The electron diffraction pattern of a single ZnWO_4 nanorod (Fig. 5c) obtained by focusing the electron beam perpendicular to the longitudinal axis presented in Fig. 5b. The SAED pattern revealed the product is a single-crystalline nature of the nanorods which can be index to (021), (121) and (100) planes with [01–2] as zone axis. So the nanorods grew preferentially along the [021] direction, which was parallel to the (100) face. The HRTEM image showed only one periodic fringe spacing which

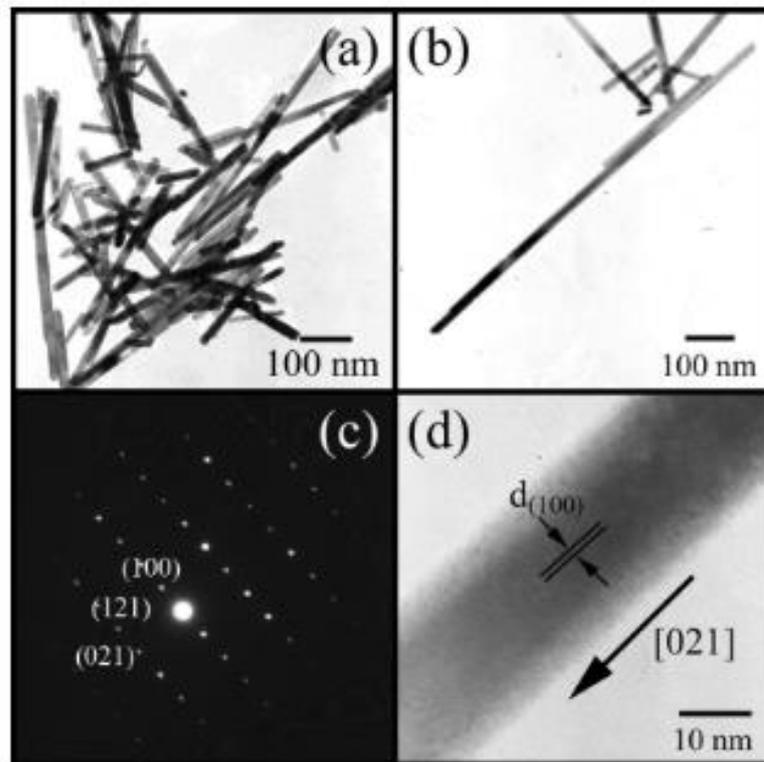

Fig. 5. TEM, HRTEM images and SAED pattern of ZnWO_4 sample.

confirmed that nanorod is a nanocrystalline structure. The lattice spacing of nanorod is along the longitudinal axis of the growth direction of nanorods which lattice spacing is 0.4674 nm which corresponded to the (100) plane of monoclinic ZnWO_4 , as marked by an arrow in Fig. 5d. It confirms that the single ZnWO_4 nanorod is grow along the [021] direction.

Fig. 6 presents TEM and HRTEM images and SAED pattern of as-synthesized 2% La-doped ZnWO_4 sample. TEM image show that the product is rod-like in shape, which indicates the symmetrical growth of nanorods along a certain direction. It can be seen that the nanorods are about 10–25 nm in diameter and 60–600 nm in length with aspect ratio of 6–24. SAED pattern is essentially identified over the entire rod from individual ZnWO_4 nanorod in Fig. 6b, indicating the brightness spot pattern. It presents that product is a single-crystalline nature. SAED pattern revealed the (021), (121) and (100) plans in zone axis of [01–2] in accordance with the XRD result. Fig. 6d reveals the HRTEM image of 2% La-doped ZnWO_4 . A lattice spacing of about 0.4673 nm can be observed, corresponding to the separation between the (100) planes of 2% La-doped ZnWO_4 . It indicates that the growing plane and the growing direction of the nanorods are in the [021] direction, as marked by an arrow in Fig. 6d. Thus, both ZnWO_4 and 2% La-doped ZnWO_4 have the same growth direction along [021] which were confirmed by SAED and HRTEM results.

The optical absorption of the as-synthesized ZnWO_4 and La-doped ZnWO_4 nanorods was measured by UV-visible spectroscopy in wavelength of 200–800 nm in ethanol solution as shown in Fig. 7a. All samples show the spectra with two shoulder absorptions at around 240–260 nm and 280–290 nm

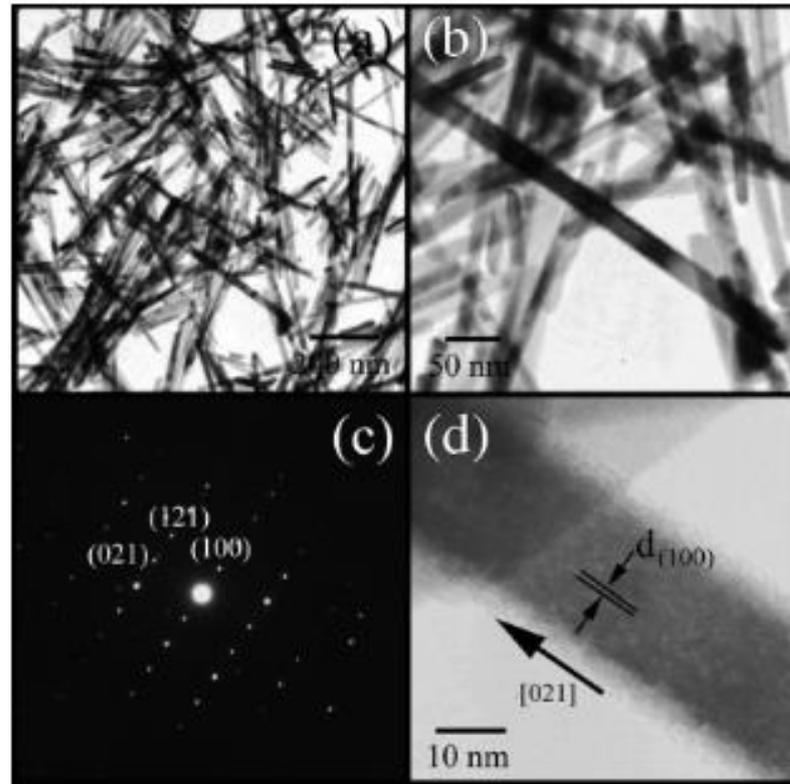

Fig. 6. TEM, HRTEM images and SAED pattern of as-synthesized 2% La-doped ZnWO₄ sample.

which assigned to be the intrinsic band gap transition. The band gaps of the as-synthesized ZnWO₄ nanorods were calculated by the below equation.

$$\alpha h\nu = (h\nu - E_g)^n \quad (1)$$

where α is the absorbance, h the Planck constant, ν the photon frequency, E_g the energy gap, and n the pure numbers associated with the different types of electronic transitions [1,14,17,18]. For $n = 1/2, 2, 3/2$ and 3 , the transitions are the direct allowed, indirect allowed, direct forbidden, and indirect forbidden, respectively. The value of n for ZnWO₄ equals to $1/2$ and its band gap was estimated to be 3.59, 3.53, 3.36, 3.24 and 3.11 eV for ZnWO₄, 0.2% La-doped ZnWO₄, 0.6% La-doped ZnWO₄, 1.0% La-doped ZnWO₄ and 2.0% La-doped ZnWO₄, respectively. It is worth to note that the La content in ZnWO₄ plays the role in decreasing the energy band gap.

4. Conclusions

In this research, 0–2% La doped ZnWO₄ nanorods have been synthesized by hydrothermal method. XRD patterns of pure ZnWO₄ and La doped ZnWO₄ samples are a wolframite monoclinic ZnWO₄ structure. Raman and FTIR spectra show a vibration of Zn–O, W–O and Zn–O–W in WO₆ and ZnO₆ octahedra. HRTEM image and SAED pattern confirmed that the nanorods grew preferentially along the [021]

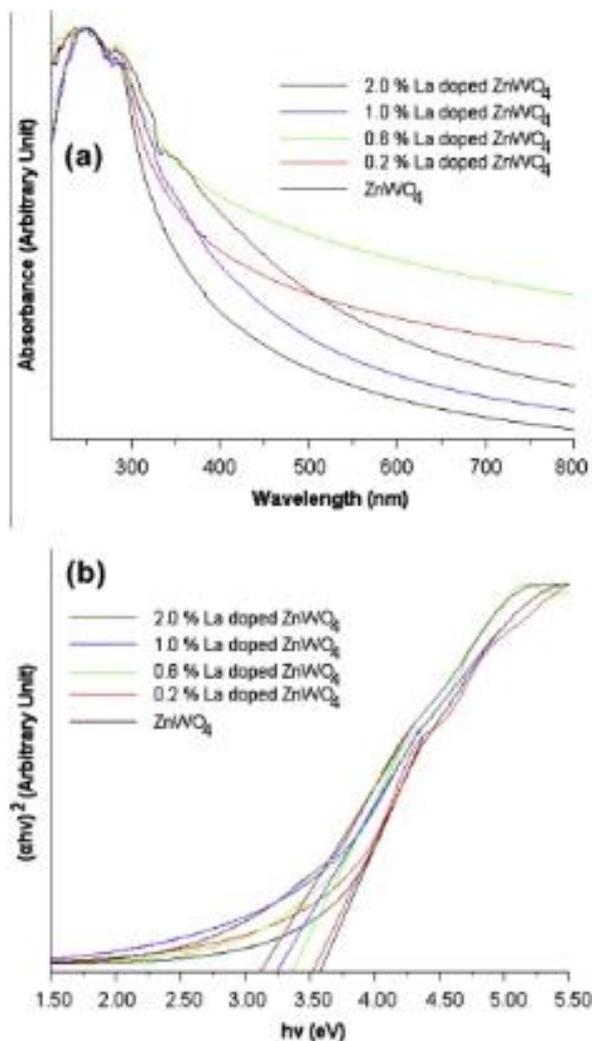

Fig. 7. (a) UV-visible spectra and (b) $(\alpha hv)^2$ vs $h\nu$ curves of products.

direction. The UV-visible spectra show the great absorbance in UV region assigned to be the intrinsic band gap transition.

Abstract Solutions containing zinc nitrate hexahydrate (Zn(NO₃)₂·6H₂O) and potassium titanium oxalate dihydrate (C₄K₂O₆Ti·2H₂O) with different molar ratios of Zn:Ti at a pH of 10 were hydrothermally processed at 120, 160, and 200 °C to form ZnO–anatase, ZnO–anatase–rutile and ZnO–rutile nanocomposites. Upon subsequent calcination the precursors at high temperatures, ZnTiO₃, Zn₂TiO₄, and Zn₂Ti₃O₈ nanoparticles were synthesized. X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), selected area electron diffraction (SAED), Fourier transform infrared (FTIR) spectroscopy, Raman spectrophotometry, and photoluminescence (PL) spectroscopy revealed the existence of nanocomposites and nanoparticles with strong emission at 386 nm for Zn₂TiO₄ and Zn₂Ti₃O₈ and at 370 nm for ZnTiO₃.

Introduction

Size dependence of nanoparticles during solid–solid phase transition is one of the most interesting nanotechnologies because the nanoparticles can play an important role in bridging bulk materials (250–1000 nm), atomic/molecular structure (50–250 nm), and even quantum-size effect (<50 nm). Physical properties of bulk materials are constant, but nanosize-dependent properties are generally varied. Basing on the melting point of nanoparticles, the thermal behaviors are inverse size dependence in phase transition temperature due to the direct correlation of volume–surface ratio. For condensed form of fine powder, irregular particle size and shape can lead to non-uniform packing morphology and density. Thus, the properties of materials change as their size approaches nanoscale. The atoms on the surface of materials are the key step to improve functionality and are significant for industrial and military sectors [1–4].

Zinc titanate (ZTO) is a low-temperature calcining dielectric material. The ZnO–TiO₂ system contains Zn₂TiO₄ (zinc orthotitanate) with inverse spinel structure, ZnTiO₃ (zinc metatitanate) with hexagonal structure and cubic Zn₂Ti₃O₈ structure (zinc polytitanate). ZTO has been widely used as a catalyst and pigment in industries. It can be used as an efficient sorbent material for removal of multiple contaminants in high-efficiency energy conversion processes. Current technologies use a multistage process (expensive) for the removal of contaminations. ZTO is cheaper and more efficient in removing of contaminants from hot coal gases. Nanoscale ZTO is expected to achieve low-temperature sintering, which is a desired property of microwave dielectrics [5–12]. The degree of crystallinity of semiconducting titanate-type compounds showed difference photoluminescence (PL) phenomena. Previously, high crystalline titanate materials showed higher photoluminescence emission than amorphous materials. This effect has been widely studied for optical-electronic applications [13–16].

ZnO–TiO₂ nanoparticles with high surface area to volume ratio provide reduction of melting point of materials by reduction their size. This phenomenon is very interesting in nanomaterials, which are melted at a temperature hundreds of degrees lower than their bulks. Melting-point depression can create a large driving force for diffusion, especially at elevated temperature [17]. ZnTiO₃, Zn₂TiO₄, and Zn₂Ti₃O₈ phases are ready to form because of their thermodynamic stability, precisely stoichiometric amount of ZnO–TiO₂ nanocomposites, and the effect of spinel structure. Previously, coarse particles require a large amount of energy to produce the titanate. Based on the ZnO–TiO₂ phase diagram, they require more than 820 °C, which can cause some competition reaction: decomposition of ZnTiO₃ into Zn₂TiO₄ + TiO₂ (rutile), Zn₂Ti₃O₈ into ZnTiO₃ + TiO₂ (rutile) and interfere the synthesis of pure phase [18–21].

The synthetic strategies are to synthesize ZnTiO₃, Zn₂TiO₄, and Zn₂Ti₃O₈ nanoparticles with high surface area to volume ratio. The process consumes short reaction time, rapid rate, and low temperature. The products were further characterized and the experimental results were investigated and discussed in this report.

Experiment

Preparation of ZnO-TiO₂ nanocomposites

Based on the chemical solution process, an analytical grade of 0.000, 0.100, and 0.200 mol zinc nitrate hexahydrate (Zn(NO₃)₂·6H₂O) each was dissolved in 100 mL de-ionized water to form solutions to which ammonium hydroxide (NH₄OH) was slowly dropped until the pH was 10 and the solutions were transparent. Then 0.100 mol potassium titanium oxalate dihydrate (C₄K₂O₆Ti·2H₂O) in 100 mL de-ionized water each was slowly mixed with the transparency solutions with keeping the pH at 10 throughout the process. These solutions were hydrothermally processed at different temperatures and lengths of time. Subsequently, the samples processed from different molar ratios were calcined at high temperatures and lengths of time, as summarized in Table 1.

Characterization

The as-prepared products were characterized by an X-ray diffractometer (XRD, SIEMENS D500) operating at 20 kV and 15 mA, a scanning electron microscope (SEM, JEOL JSM-6335F) operating at 15 kV with LaB₆ as a cathode for electron gun, a transmission electron microscope (TEM, JEOL JEM-2010), and selected area electron diffraction (SAED) operating at 200 kV, a Fourier transform infrared spectrometer (FTIR, Bruker Tensor 27) with KBr as a diluting agent operating in the range of 4000–400 cm⁻¹, a Raman spectrometer (T64000 HORIBA Jobin-Yvon) using a 50 mW and 514.5 nm wavelength Ar green laser, and a photoluminescence

Results and discussion

The nanocomposites were hydrothermally processed at different temperatures and lengths of time, and the XRD results are shown in Fig. 1. In this research, the products prepared from 0:1 to 2:1 molar ratios of Zn:Ti by hydrothermal process at

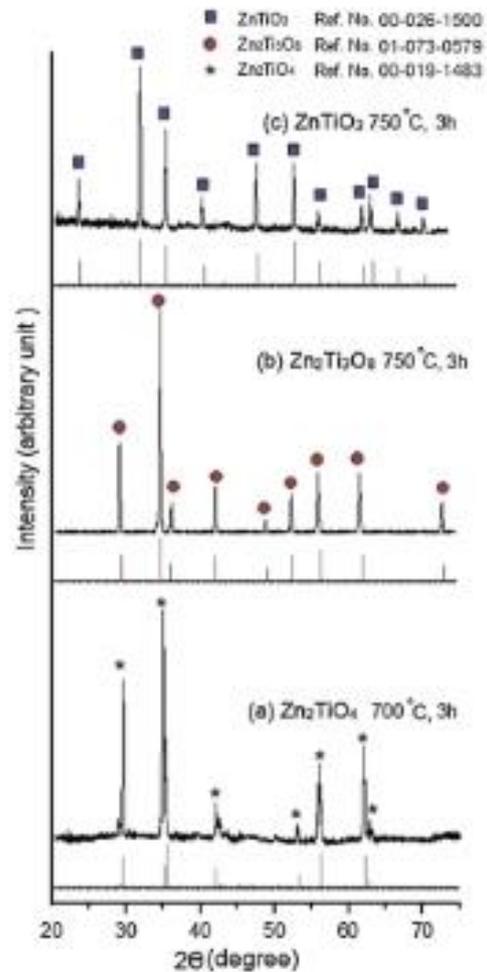

Fig. 1 XRD patterns of the product precursors synthesized by hydrothermal process at different temperatures and lengths of time: **a** ZnO–anatase, **b** ZnO–anatase–rutile, and **c** ZnO–rutile composites

120 °C for 12 h were composed of anatase, and wurtzite ZnO–anatase composites (JCPDS no 00-004-0477 for anatase and 00-005-0664 for ZnO) [22], respectively. Upon being hydrothermally processed, the mixture with 2:1 molar ratio of Zn:Ti at 160 °C for 24 h, additional rutile (JCPDS no 00-004-0551) [22] was also detected. For hydrothermal processing of the mixture with 1:1 molar ratio of Zn:Ti at 200 °C for 48 h, wurtzite ZnO–rutile composites were detected. At this condition, the whole anatase phase was transformed into the rutile phase.

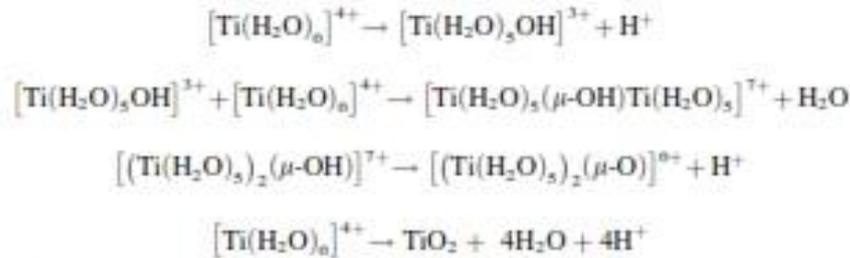

The precursors were further calcined at different temperatures and lengths of time, as the XRD results show in Fig. 2. The hydrothermal sample processed from 1:1 molar ratio of Zn:Ti at 200 °C for 48 h and further calcined at 750 °C for 3 h was the ZnTiO₃ phase (JCPDS no. 00-026-1500) [22]. The sample hydrothermally processed from a 2:1 molar ratio of Zn:Ti at 120 °C for 12 h, and further calcined at 700 °C for 3 h leads to detect the Zn₂TiO₄ phase (JCPDS no. 00-019-1483) [22]. The mixture of as-prepared Zn₂TiO₄ and as-prepared anatase in a 1:2 molar ratio

Fig. 2 XRD patterns of **a** Zn₂TiO₄, **b** Zn₂Ti₃O₈, and **c** ZnTiO₃

was calcined at 750 °C for 3 h, and the $Zn_2Ti_3O_8$ phase (JCPDS no. 01-073-0579) [22] was detected.

Upon dissolving of $C_4K_2O_6Ti \cdot 2H_2O$ in water, the pH dropped down to 4.3. Generally, titanium ions exist in aqueous solution as hexaaqua coordination $[Ti(H_2O)_6]^{4+}$ complex [23]. When NH_4OH was slowly added to the solution, an O–H bond of $[Ti(H_2O)_6]^{4+}$ complex was broken by transforming into a hydroxide complex or the conjugate base of the $[Ti(H_2O)_6]^{4+}$ complex. The hydroxide complex withstood olation reaction, originated by releasing of one water molecule and combining with a neighboring complex. Under kinetic control of the olation reaction, bridging ligands start from *cis*-coordination reaction to form anatase structure. For thermodynamic control at high temperature, nuclei of the olation product starts from the *trans*-coordination reaction to form a rutile structure. Hydroxide ligands were bridged (denoted by μ) between two titanium atoms. During the process, ionization and condensation kept going even at high pH. In the end, anatase TiO_2 was obtained.

In this research, anatase is considered a metastable phase due to the *cis*-coordination reaction under kinetic control at low temperature and short length of time. Rutile is a thermodynamic controlling phase at higher temperature and longer time. During processing, nuclei formed and grew to be crystals, originating from the order of TiO_6 octahedral units: zigzag for anatase and linear for rutile. The zigzag uses only the *cis*-coordination for crystal growth, but the linear requires the *trans*-coordination to bridge two octahedral units. The bridging structure is unstable under kinetic control process but the linear packing is the thermal stable structure due to the closest packing of TiO_6 octahedral units. The kinetic and thermodynamic models support the irreversible process of anatase. The anatase favors to form specific titanate (Zn_2TiO_4 and $Zn_2Ti_3O_8$) because *cis*-transformation tends to form under cubic crystal system. The TiO_2 , Zn_2TiO_4 , $Zn_2Ti_3O_8$, and $ZnTiO_3$ phases consist of TiO_6 octahedrons connected through a common edge. The anatase and spinel-like structures (Zn_2TiO_4 and $Zn_2Ti_3O_8$) have common 3D frameworks. Moreover, rutile and $ZnTiO_3$ are composed of TiO_6 octahedral layers [23]. The formation of Zn_2TiO_4 and $Zn_2Ti_3O_8$ limited by the presence of anatase and $ZnTiO_3$ can form in the presence of rutile. The following decomposition reactions are

In this research, the ZTO can be synthesized at lower temperatures than 820 and 945 °C. By using the nanoprecursors, the calcination temperatures can be reduced to 700 °C for the synthesis of Zn₂TiO₄ and to 750 °C for the synthesis of ZnTiO₃ and Zn₂Ti₃O₈, as the XRD patterns shown in Fig. 2.

Figure 3 shows the morphologies and BET surface areas of ZnO-TiO₂ nanocomposites, ZnTiO₃, Zn₂TiO₄, and Zn₂Ti₃O₈. ZnO-anatase nanocomposites synthesized at 120 °C for 12 h have the average diameter of <10 nm and surface area of 215.58 m²/g that are appropriate for melting-point depression [23]. ZnO-anatase-rutile (151.62 m²/g) and ZnO-rutile (148.06 m²/g) nanocomposites became larger in sequence because they were synthesized at 160 °C for 24 h and at 200 °C for 48 h, respectively. Upon calcination the ZnO-anatase nanocomposites at 700 °C for 3 h, the Zn₂TiO₄ nanoparticles with the surface area of 52.49 m²/g were produced. Different atoms in the materials diffused across the boundaries of the

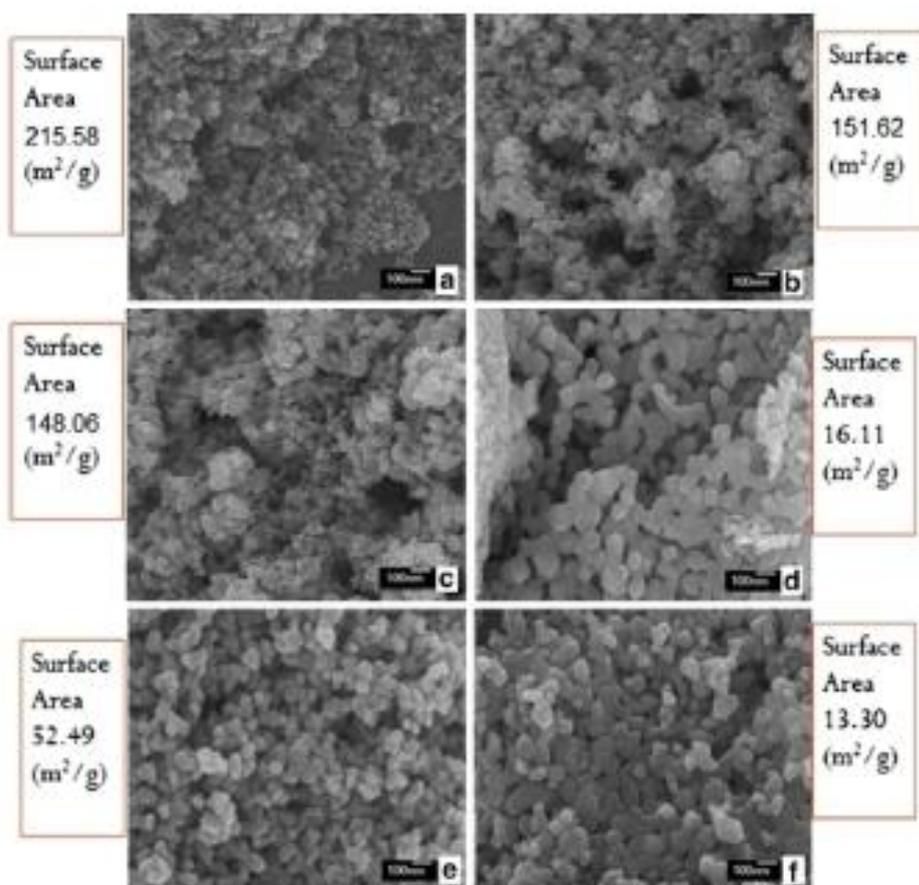

Fig. 3 SEM images and surface areas of the a ZnO-anatase, b ZnO-anatase-rutile, c ZnO-rutile, d ZnTiO₃, e Zn₂TiO₄, and f Zn₂Ti₃O₈ samples

particles. ZnO–anatase nanocomposites were chemically transformed into Zn_2TiO_4 nanoparticles with subsequent clustering together to form larger nanoparticles. During processing, counter diffusion of Zn^{2+} and Ti^{4+} could proceed as well. $ZnTiO_3$ nanoparticles were produced by calcination of ZnO–rutile nanocomposites with 1:1 molar ratio of Zn:Ti at 750 °C for 3 h. Their surface area was decreased to 16.11 m²/g. Upon calcination the Zn_2TiO_4 -anatase nanocomposites at 750 °C for 3 h, $Zn_2Ti_3O_8$ nanoparticles with surface area of 13.30 m²/g were produced.

To understand further the nanostructure and phase of the products, ZnO–anatase, $ZnTiO_3$, Zn_2TiO_4 , and $Zn_2Ti_3O_8$ were characterized by TEM (Fig. 4) and SAED (Fig. 5). The TEM bright field image illustrates ZnO–anatase, which was composed of very tiny nanoparticles (<10 nm diameter) and the corresponding SAED pattern of ZnO–anatase nanocomposites. In general, the melting temperature (T_m) of nanoparticles is considered to be controlled by particle size. For nanoparticles, the surface area to volume ratio is large and the surface curvature is high. The melting temperature is size dependent and is the main objective to synthesize the

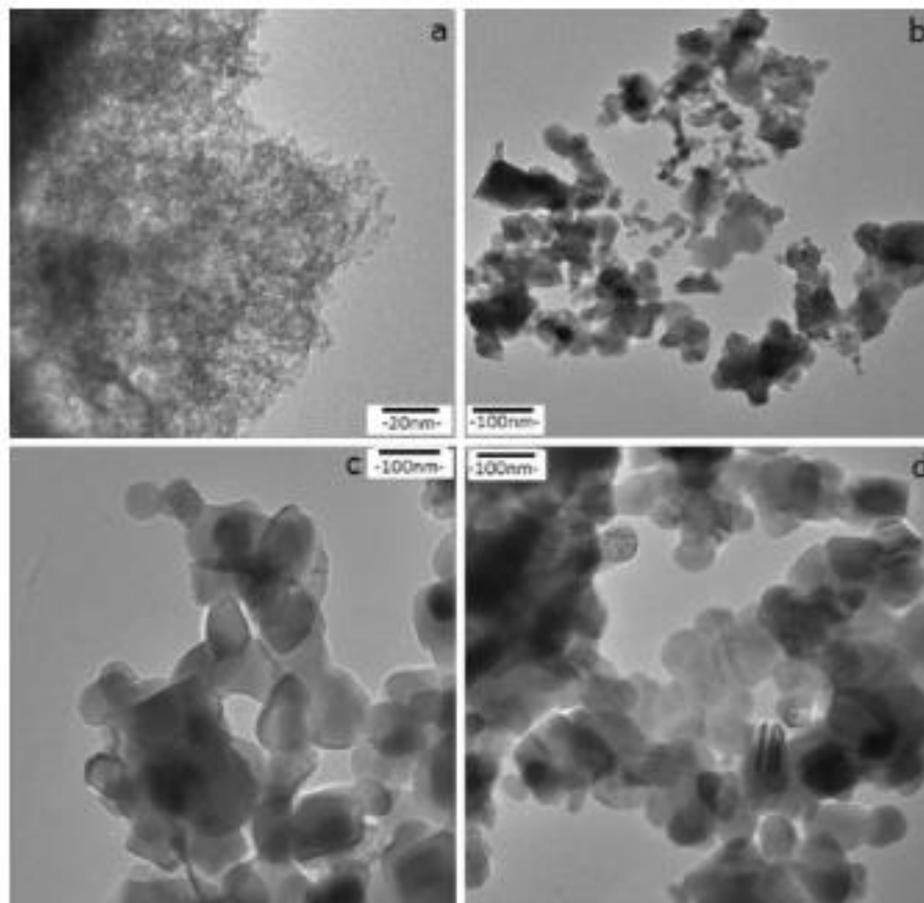

Fig. 4 TEM images of **a** ZnO–anatase, **b** $ZnTiO_3$, **c** Zn_2TiO_4 , and **d** $Zn_2Ti_3O_8$ nanoparticles

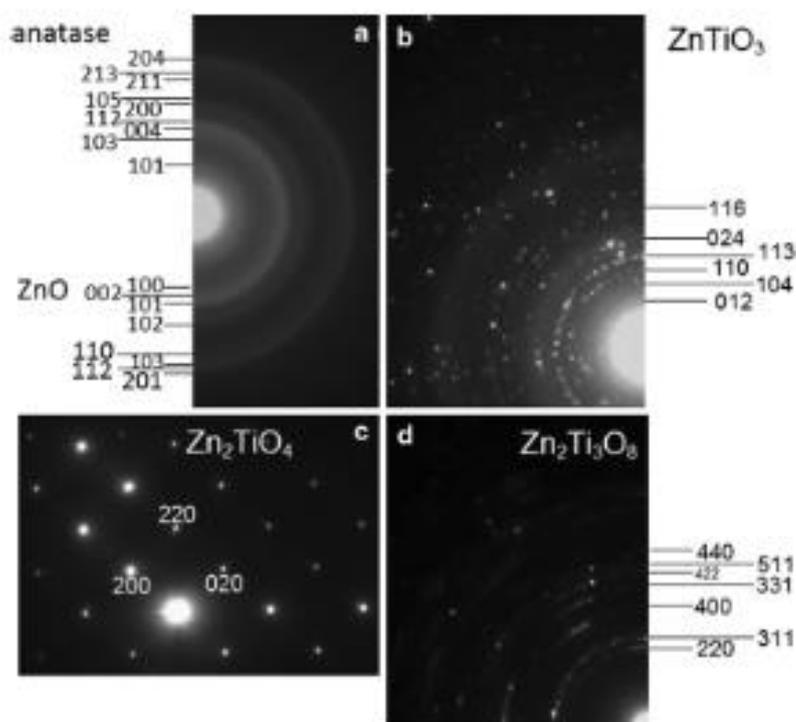

Fig. 5 SAED patterns of a ZnO-anatase, b ZnTiO₃, c Zn₂TiO₄, and d Zn₂Ti₃O₈ nanoparticles

nanocomposites by low temperature calcination. The thermodynamic behavior has been explained and shown by an experimental procedure [24]. The SAED ring-pattern of ZnTiO₃ nanoparticles with the size range of 50–100 nm corresponding to the lattice fringe of the (012), (104), (110), (113), (024), and (116) planes is in accordance with the above XRD analysis. The present analysis shows the Zn₂TiO₄ fine nanoparticles with 40–80 nm average size and its corresponding SAED pattern with the [001] direction as zone axis. The Zn₂Ti₃O₈ sample was composed of a number of nanoparticles with 50–100 nm size range orientated in different directions, including the ring pattern containing the (220), (311), (400), (331), (422), (511), and (440) lattice planes.

Photoluminescence (PL) of the zinc titanate samples taken with an excitation wavelength of 250 nm is shown in Fig. 6. Both Zn₂TiO₄ and Zn₂Ti₃O₈ show strong PL emission at 386 nm and a weak band at 325 nm. Weak violet emission of Zn₂TiO₄ and Zn₂Ti₃O₈ was detected at 280 nm. In contrast, ZnTiO₃ shows a strong PL peak at 370 nm only. This detection belongs to hexagonal limonite type ZnTiO₃ [25]. Base on the SAED and TEM results, Zn₂TiO₄ is the only single perfect crystal with the highest degree of crystallinity. Thus, Zn₂TiO₄ has the highest PL intensity. The second PL intensity is Zn₂Ti₃O₈ because its formation reaction may cause a reduction in crystallinity, become more disordered polycrystal, and result in quenching of PL sensitivity. It was not the lowest intensity because single crystalline Zn₂TiO₄ used as the precursor is the best crystallinity. In contrast,

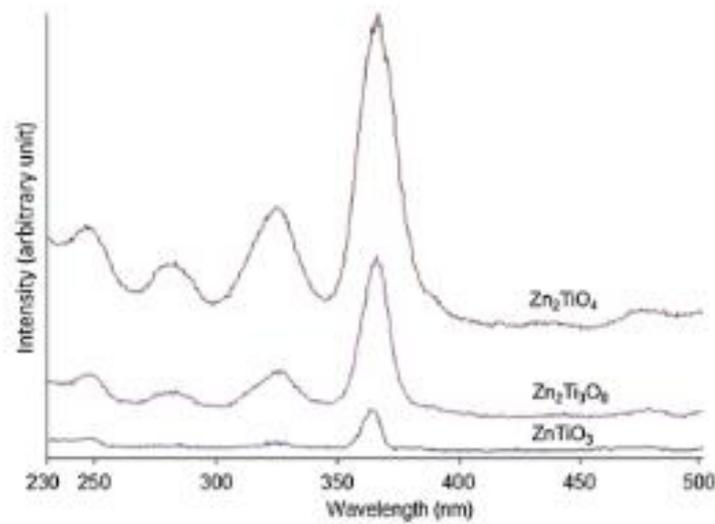

Fig. 6 Photoluminescence of ZnTiO_3 , $\text{Zn}_2\text{Ti}_3\text{O}_8$, and Zn_2TiO_4

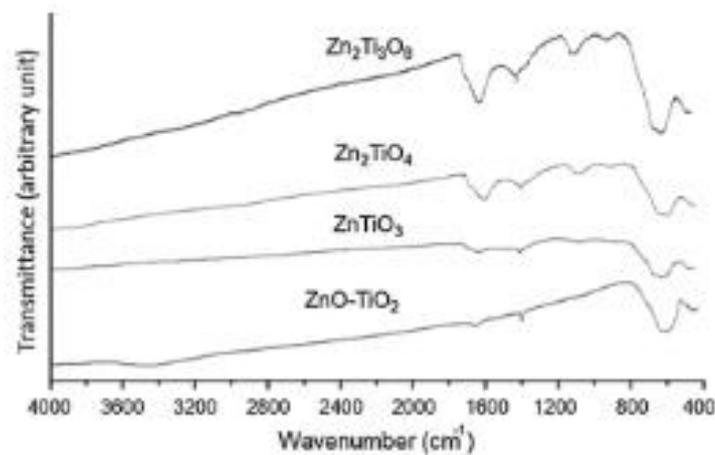

Fig. 7 FTIR spectra of ZnO -anatase, ZnTiO_3 , Zn_2TiO_4 , and $\text{Zn}_2\text{Ti}_3\text{O}_8$

ZnTiO_3 has the lowest PL intensity because the transformation of the stable rutile phase and ZnO to the titanate was very difficult comparing to that of the metastable anatase phase. This process can lead to real material system that always incorporate with disordered amorphous material. Different defects in the lattice can be caused by variation of the chemical constituents, as reported for the ZTO non-optical material [13, 14].

FTIR spectra of ZnO -anatase, ZnTiO_3 , Zn_2TiO_4 , and $\text{Zn}_2\text{Ti}_3\text{O}_8$ are shown in Fig. 7. Vibration modes of $[\text{TiO}_6]$ and Zn-O-Ti groups existing in different phases of the products were detected at $550\text{--}650$ and 735 cm^{-1} , respectively. The wavenumber for Ti-O octahedral absorption of titanate increased with decrease in

Zn:Ti molar ratio. The ZnO₄ stretching vibration was detected at 400–500 cm⁻¹. Some residual oxalate groups were detected at 1400–1600 cm⁻¹ [24].

Raman spectra of ZnO-anatase, Zn₂TiO₄, Zn₂Ti₃O₈, and ZnTiO₃ are shown in Fig. 8. ZnO has a wurtzite crystal structure with P6₃mc space group. Its vibration modes are generally predicted by the optical theory group A₁ + 2E₂ + E₁ + 2B₁ [4]. The A₁ and E₁ phonon modes are both Raman and IR active, the E₂ mode is only Raman active, and the B₁ mode is forbidden. The strong and sharp peak at 435 cm⁻¹ can be assigned to the high frequency of E₂, indicating that ZnO nanoparticles are good hexagonal oxide. The hexagonal ZnO revealed the Raman vibration at 320, 370, 405, and 575 cm⁻¹, assigned as the E_{2H}-E_{2L}, A₁(TO), E₁(TO), and E₁(LO) symmetrical phonon modes, respectively. The anatase was characterized to have five Raman active modes at about 153 cm⁻¹ (E_g), 203 cm⁻¹ (E_g), 390 cm⁻¹ (B_{1g}), 515 cm⁻¹ (A_{1g} + B_{1g}), and 605 cm⁻¹ (E_{1g}). There are five Raman-active phonon modes (A_{1g} + E_g + 3F_{2g}) in the cubic spinel Zn₂TiO₄, as the results summarize in Table 2. The Raman vibrational modes at 257, 305, 380, 470, and 722 cm⁻¹ were assigned as F_{2g}, E_g, F_{2g}, F_{2g}, and A_{1g} symmetrical phonon modes, respectively. Zn₂Ti₃O₈ has a cubic spinel structure with five Raman-active phonon modes (A_{1g} + E_g + 3F_{2g}). The vibrations were detected at 245, 310, 470, 520, and 718 cm⁻¹ and were assigned as the F_{2g}, E_g, F_{2g}, F_{2g}, and A_{1g} symmetrical phonon modes, respectively. According to group theory, ZnTiO₃ (point group C3i) has 10 Raman active modes: 5A_g + 5E_g. The Raman vibration of ZnTiO₃ was detected at 152, 188, 230, 262, 348, 403, 472, 486, 622, and 717 cm⁻¹ and were specified as the E_g, A_g, E_g, A_g, A_g, E_g, E_g, A_g, E_g, and A_g symmetrical phonon modes, respectively.

Conclusions

ZnO–TiO₂ (anatase/rutile) nanocomposites were successfully synthesized by a hydrothermal method. The samples were transformed into Zn₂TiO₄ nanoparticles by calcination of ZnO–anatase at 700 °C for 3 h and ZnTiO₃ nanoparticles by calcination of ZnO–rutile at 750 °C for 3 h. The Zn₂Ti₃O₈ sample was able to be synthesized by calcination of Zn₂TiO₄–anatase composites at 750 °C for 3 h. The Zn₂TiO₄ and Zn₂Ti₃O₈ samples show strong emission at 386 nm and ZnTiO₃ sample at 370 nm.

Chiang Mai University

Publications

- 1) Jirapong Arin, Somchai Thongtem and Titipun Thongtem, "Single-step synthesis of ZnO/TiO₂ nanocomposites by microwave radiation and their photocatalytic activities", *Material Letter*, 96 (2013) 78-81.
- 2) Jirapong Arin, Somchai Thongtem and Titipun Thongtem et al., "Synthesis, characterization and optical activity of La-doped ZnWO₄ nanorods by hydrothermal method", *SUPERLATTICE MICROST.* 67 (2014) 197-206.
- 3) A. Phuruangrat, J. Arin, S. Thongtem, T. Thongtem et al., "Synthesis, characterization and optical activity of La-doped ZnWO₄ nanorods by hydrothermal method", *Rare Metals*. 35 (2016) 390-395
- 4) J. Arin, A. Phuruangrat, S. Thongtem and T. Thongtem, "Characterization of ZnO-TiO₂ and zinc titanate nanoparticles synthesized by hydrothermal process" *Res. Chem. Intermed. (Article in pressed)* (2016)

Experiences

- 1) Jirapong Arin, Somchai Thongtem and Titipun Thongtem, "Synthesis of La-doped ZnO-TiO₂ Nanocomposites by cyclic-microwave radiation method and

Their Photocatalytic Activities” The Fourth International Conference on
Science, Technology and Innovation for Sustainable Well-Being (STISWB IV),
10-12 August 2012, Thailand.
